Summary of standard extreme-value statistics:

² Let z_1 ;:::; z_N be i.i.d. random variables with probability density function p(z). Let $y_N = \max_{i=1;:::;N} f z_n g$ be **maximum** of the set, and $F_N(y) = P \operatorname{rob}(y_N < y)$ be the **distribution of the maximum**. Then for $N \ A \ 1$ the distribution approaches a **scaling form** $F_N(y) \ \% F_1 [(y + a_N) = b_N]$ where a_N ; b_N depend on p(z) but the shape of F_1 is **universal**, and given by

The result is rather robust if variables are short-range correlated. In particular, for Gaussian-distributed variables with $\langle z_i \rangle = 0$ the **Gumbel** distribution is known to be valid as long as $C(ji \ j \ j) = hz_iz_i \ i \leq const = \ln ji \ j \ j$ for $ji \ j \ j \ A$ 1.

Very few explicit results exist for extrema of **strongly correlated variables**, as e.g. for Brownian motion by **Majumdar** & **Comtet**, or for the largest eigenvalues of random matrices by **Tracy & Widom**.

Gaussian Free Field: definition:

² Given any domain **D** consider the **Laplace** operator $j \in A$ and denote $\mathbf{e}_j(\mathbf{x})$ and $\mathbf{g}_j > 0$ for $j = 1, 2, \dots, 1$ its eigenfunctions/eigenvalues corresponding to the Dirichlet boundary conditions. Then the functions $\mathbf{e}_j(\mathbf{x}) = \mathbf{p}_{\mathbf{g}_j} \mathbf{e}_j(\mathbf{x})$ form an orthonormal basis of the Hilbert space H w.r.t. the so-called **Dirichlet** scalar product

$$(f;g) = \frac{Z}{I}$$

Gaussian Free Field: examples:

² **GFF** on the interval $P_{\overline{2}} = [0;1]$. Eigenf./eigenv. for the Laplacian $= i \frac{d^2}{dx^2}$ (Dirichlet b.c.): $e_n(x) = \sum_{n=1}^{\infty} \frac{1}{n} \frac{d^n}{dx^n} = i \frac{d^n}{dx^n} \frac{d^n}{dx^n}$. The corresponding GFF is given by the random Fourier series $V(x) = \sum_{n=1}^{\infty} \frac{1}{3n} \frac{d^n}{dx^n} \sin n \frac{dx}{dx}$, with the covariance given by the Green function $G(x_1; x_2) = \min(x_1; x_2)[1; \max(x_1; x_2)]$ - **Brownian bridge**.

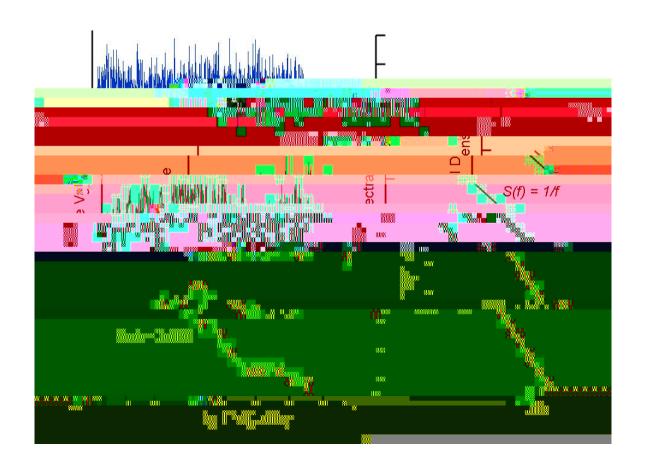

² **GFF** on the two-dimensional disk: $\mathbf{D} = jzj < L$ where z = x + iy. The Green function is given by $G(z_1; z_2) = i \frac{1}{2^{1/4}} \ln \frac{Ljz_{1i} z_2j}{L^2_{ij} z_1z_2}$. In particular, for any two points $jz_{1;2}j \geq L$ (i.e. well inside the disk) we recover the **full-plane** formula

$$G(z_1; z_2) = i \frac{1}{2 \frac{1}{4}} \ln \frac{j z_1 i z_2 j}{L}, \quad P[V(\mathbf{x})] / \exp i \frac{1}{2}^{\frac{7}{2}} [r V(\mathbf{x})]^2 d^2 \mathbf{x}$$

² Using the full-plane logarithmic GFF we can construct various one-dimensional Gaussian random processes with **logarithmic** correlations. In particular, sampling the values of such GFF along a circle of unit radius with coordinates $z = e^{it}$; t = 2 [0; 2½) we get a Gaussian process with mean zero and the covariance

$$hV(t_1)V(t_2)i = i \frac{1}{2\frac{1}{4}} \ln j e^{it_1} i e^{it_2} j$$

Such a process turns out to be equivalent to the random Fourier series of the form $V(t) = \int_{n=1}^{1} \sqrt{p_n} v_n e^{int} + \nabla_n e^{i-int}$, where v_n ; ∇_n are i.i.d. complex Gaussian variables with variance $hv_n\nabla_n i = 1$. As the power associated with a given Fourier harmonic with index n decays like 1=n such signals are known as 1=f noises believed to be ubiquitous in Nature.

Problem:

²Given an instance of the full-plane 2D Gaussian free field:

$$P[V(\mathbf{x})] / \exp_i \frac{1}{8 \frac{1}{4} g^2} \left[rV(\mathbf{x}) \right]^2 d^2 \mathbf{x}$$

characterized by the covariance

$$hV(\mathbf{x}_1)V(\mathbf{x}_2)i = j \ 2g^2 \ln j\mathbf{x}_1 j \ \mathbf{x}_2 j$$

we wish to understand the statistics of its minima/maxima along various curves in the plane, and ultimately in various planar domains.

² The problem turns out to be intimately connected to the mechanism of **freezing transitions** in disordered systems theory (Random Energy Models, Dirac fermions in random magnetic field). It has also interesting relations to **Liouville Quantum Gravity** & conformal field theory, to **multifractal** random measures, 1=f **noises**, and processes arising in turbulence and mathematical finance, as well as to various aspects of **Random Matrix Theory**.

Idea of the method: We concentrate on considering samples of the full-plane Gaussian Free Field (2dGFF) along planar curves \mathcal{C} parametrised by $\mathbf{x}(t) = (x(t); y(t))$ with real $t \ 2[a;b]$. Given a measure $d^{1}_{\mathcal{B}}(t) = \frac{1}{2}(t) \ dt$, we consider the integral

$$Z^{-} = 2^{-2}g^{2} e^{i - V_{2}(\mathbf{x}(t))} d^{1}_{1}(t); - > 0$$

where $V_2(\mathbf{x})$ is the regularized version of the 2dGFF with a short scale cutoff 2 \geq 1, i.e. zero mean and the covariance

The integral is to be interpreted as the **partition function** of the associated **Random Energy Model** at the temperature $T = {}^{-i} {}^{1}$. This is to be studied in the limit 2 ! 0.

Guiding example: CIRCULAR LOGARITHMIC MODEL:

Let the contour C be the unit circle: $x(t) = \cos t$; $y(t) = \sin t$, with t = 2[0;2%). Sample the 2d Gaussian Free Field at M equidistant points along the circle with $t_k = \frac{2\%}{M}(k_i + 1)$; k = 1; t = 1; t = 1

As the distance $j_{\mathbf{x}_1 j}$ $\mathbf{x}_2 j$ between a pair of points is simply $2j\sin\frac{t_{1j}}{2}j$, we deal with the collection of M normally distributed variables with covariances

$$hV_kV_mi = i 2g^2 \ln j2 \sin^{2/4}$$

Observation: The positive integer moments $hZ^n(\bar{\ })i$; n=1;2;::: of the partition function $Z(\bar{\ })=\int_{i=1}^{M}e^{i\bar{\ }}v_i$ for the circular logarithmic model in the high-temperature phase $\bar{\ }=\bar{\ }^{-2}g^2<1$ turn out to be given in the thermodynamic limit M A 1 by

$$hZ_{circ}^{n}(\ \)i=\frac{M^{1+\ ^{\circ}n^{2}}O(1)}{M^{(1+\ ^{\circ})n}D_{n}(\ ^{\circ})} \quad n>1=\ ^{\circ}$$

where $D_n(^{\circ})$ is the **Dyson-Morris** Integral

$$D_n(^{\circ}) = \frac{1}{(2 \frac{1}{4})^n} \int_{0}^{Z_{2\frac{1}{4}}} d\mu_1 ::: \int_{0}^{Z_{2\frac{1}{4}}} d\mu_n$$

Outcome of the analysis:

The probability density P(Z) of the partition function $Z_{circ}(\bar{\ })$ $\bar{\ }Z$ in the high-temperature phase $^{\circ} = ^{-2}g^2 < 1$ consists of two pieces. The "body" of the distribution is given by:

$$P(Z) = \frac{1}{2} \frac{1}{Z} \frac{1}{Z} \frac{Z_e}{Z} e^{i\left(\frac{Z_e}{Z}\right)^{\frac{1}{2}}}; \quad Z \geq M^2$$

which has a pronounced maximum at $Z \gg Z_e = \frac{M^{1+°}}{i(1i^°)} \geq M^2$, and the powerlaw decay at $Z_e \geq Z \geq M^2$.

At $Z \hat{A} M^2$ the above expression is replaced by the **lognormal tail**:

$$P(Z) = P \frac{M}{4 \% \ln M} \frac{1}{Z} f^{ij} \frac{\ln Z}{2 \ln M} e^{ij} \frac{1}{4 \ln M^{\circ}} \ln^{2} Z \quad \text{where } f(x) \gg O(1) \text{ for } x \gg O(1)$$

Now we define $z=Z=Z_{e}$, put the coupling constant g=1 and consider the generating function

$$g^{-}(x) = \exp(i e^{-x}z)^{\otimes}_{MA1}$$
; $- = 1=T$

<u>Freezing scenario</u>: In the high-temperature phase $\bar{c} < \bar{c} = 1$ the generating function $g_{\bar{c}}(x)$ can be found explicitly and turned out to satisfy a remarkable duality relation:

$$g^{-}(x) = \int_{0}^{\pi} dt \exp i t_{i} e^{-x} t_{i}^{-2}$$
; $g^{-}(x) = g_{\underline{1}}(x)$:

This however does not allow to continue to $\bar{} > \bar{}_c$ regime. The phase transition at $\bar{} = \bar{}_c$ is believed to be described by the following **freezing scenario**: $g_-(x)$ **freezes** to the **temperature independent** profile $g_-(x)$ in the "glassy" phase $T_-(x)$. The scenario is supported by (i) a heuristic **real-space renormalization group arguments** for the logarithmic models (**Carpentier**, **Le Doussal '01**) revealing an analogy to the **travelling wave** analysis of polymers on disordered trees (**Derrida**, **Spohn 1989**)

(ii) duality which implies

$$@-g-(x)j_{-}=-j_{c}=0$$
 ; for all x

showing that the "temperature flow" of this function vanishes at the critical point $\bar{c} = \bar{c} = 1$ (iii) our **numerics**.

Assuming validity of such scenario for the problem in hand, one finds the frozen profile for the circular model:

$$g_{\bar{c}}^{circ}(x) = 2e^{x=2}K_1(2e^{x=2})$$

where $K_1(z)$ is the Macdonald function. This allows to reconstruct the **distribution of the free energy** $f = i^{-i} \ln z$ for any $T < T_c$. The corresponding formula takes a form of an infinite series:

$$P_{->-c}^{CLM}(f) = \frac{1}{2^{1/4}} \int_{i}^{2\pi} e^{i i s f} \frac{1}{i (1 + \frac{i s}{2})} i^{2} \int_{1}^{2\pi} ds$$

$$= i \frac{d}{df} A + \frac{1}{n!} \int_{n=1}^{2\pi} \frac{e^{n-c f}}{n!(n i + 1)!} \int_{1}^{2\pi} \frac{1}{n^{-c}} e^{i s f} \int_{1}^{2\pi} ds$$

where $\tilde{A}(x) = \int_{1}^{\theta} f(x) dx = \int_{1}^{\theta} f(x) dx$. In the zero temperature limit $f(x) = \int_{1}^{\theta} f(x) dx = \int_{1}^{\theta}$

The minimum of the random potential is simply given by $V_{min} = i \lim_{T \neq 0} f = const + x$, with known const and the probability density of x related to the frozen profile $g_{-c}(x)$ by

$$p(x) = i g_{-c}^{\ell}(x) = i \frac{d}{dx} 2e^{x=2} K_1(2e^{x=2})^{\ell}$$
 (1)

This is different from **Gumbel** distribution $p_{Gum}(x) = i \frac{d}{dx} \exp_i Be^{Ax^{\alpha}}$.

From circles to intervals:

For integers n=1;2;::, a well defined and universal 2 ! 0 limits exist for the moments of the partition function

$$Z_{[0;1]}^n = Z_1 Z_1 Y$$

 $1 = \frac{1}{2} =$

ijext 2

Fateev, Zamolodchikov, Zamolodchikov 2000

In this way we arrive to

$$M^{-}(s) = A^{-}2^{(s_{j}-1)(2+\frac{-2}{2}(2s+1))} \frac{1}{4}^{1_{j}-s}$$

$$\mathcal{E}\frac{i(1+\frac{-2}{5}(s_{j}-1))G^{-}(\frac{1}{2}+\frac{1}{2}+\frac{-s}{5})G^{-}(\frac{3}{2}+\frac{-s}{5})G^{-}(\frac{1}{2}+\frac{3}{2}+\frac{-s}{5})}{G^{-}(\frac{1}{2}+\frac{2}{2}+\frac{-s}{5})G^{-}(\frac{1}{2}+\frac{-s}{5})^{2}}$$

with $A = \frac{G - (\frac{1}{2} + \frac{7}{2})^2 G(2^{-} + \frac{2}{2})}{G - (\frac{3}{2} + \frac{1}{2}) G - (\frac{3}{2} + \frac{7}{2}) G - (\frac{3}{2} + \frac{3}{2})}$. To guarantee that we have found the correct continuation, we have checked

- (i) positivity: M(s) given above is finite and positive on the interval s 2 [0; +1] [that is all real moments n = 1; s < 1 exist.
- (ii) convexity: on this interval $\mathcal{Q}_s^2 \ln M(s) > 0$.
- (iii) For integer values of S gives back known positive/negative moments.

We can use the above expression to extend the duality relation:

$$g_{\overline{}}(x) = g_{\underline{1}}(x) :$$

to the case of the interval [0;1].

Under the **freezing hypothesis** we extract the frozen profile $g_{c}(x)$. For the general case the expression can be obtained as expansion in powers of e^{x} for x? i 1. For example, for a = b = 0

$$g_{c}(x ! j 1) = 1 + (x + A^{\theta})e^{x} + (A + By + Cx^{2} + \frac{1}{6}x^{3})e^{2x} + \cdots$$
 (2)

with $A^{\theta} = 2^{\circ}_{E} + \ln(2\frac{\pi}{4})_{j}$ 1 and C = j 0:253846, B = 1:25388, A = j 5:09728. For the special case a = b = j 1=2 we obtain the closed form expression:

$$g_{c}(x) = \frac{\frac{1}{4} \sum_{i=1}^{N-1} e^{j \frac{t^{2}}{2^{i}} 2^{p} \frac{1}{\ln 2t}} e^{j \frac{t^{2}}{2^{i}} 2^{p} \frac{1}{\ln 2t}} e^{j \frac{t^{2}}{2^{i}} 2^{p} \frac{1}{\ln 2t}} 1_{i} \frac{e^{x}}{u} e^{j \frac{p}{\frac{1}{4}u = 2} e^{j}} e^{j \frac{p}{\frac{1}{4}u = 2} e^{j}} du$$

Although these expressions are different from the circle case, the universal Carpentier-Le Doussal tail for the probability density of extreme values

$$p(x ! j 1) = j g_{-c}^{0}(x ! j 1) \gg j x e^{x}$$

is shared by all these distributions. It has its origin in the characteristic tail of the partition function density $P(z \ \hat{A} \ 1) \ / \ 1=z^2$ developed at criticality, with the first moment < z > becoming **infinite**.

Conclusions & Discussions:

Using the methods of statistical mechanics we were able to extract the explicit expressions for distributions of extrema of the Gaussian Free Field sampled along (i) circles of unit radius and (ii) intervals of unit length. The distributions are manifestly non-Gumbel and show universal backward tail. The results are expected to describe extreme value statistics for 1=f signals, and in this way could be Our method was based on a few assumptions, most importantly (i) freezing scenario for REM-type models, and (ii) ability to continue Selberg integrals away from positive integers to the complex plane (can

be put on the rigorous basis by a method developed recently in D.

Ostrovsky Comm. Math. Phys. 288 (2009) 287-310)

It remains a challenge:

- to verify/justify the freezing scenario
- ² to understand universality of the results for other 1*d* curves
- ² to access extreme value statistics of GFF in 2D domains.
